Spotted lanternfly (SLF), *Lycorma delicatula*, is an invasive planthopper, native to Asia, that was first detected in 2014 in southeastern Pennsylvania. As of April 2021, SLF is found in Pennsylvania, New Jersey, Virginia, West Virginia, Maryland, Connecticut, Delaware, New York, and Ohio. Detections of SLF have been reported in Maine, Massachusetts, Michigan, North Carolina, California, and Oregon; however, populations are not yet known in these states. SLF feeds on many plants, including economically important crops like grapevines, cucumber, hardwoods, and ornamentals. Significant damage has been reported from SLF feeding on grapevines, including increased susceptibility to winter injury, reduced starch concentration in vine roots, reduced yield in the subsequent year, and potential death of vines. This guide will update you on our current knowledge and best management practices for this insect in vineyards.

**Life Cycle and Identification**

Spotted lanternfly is not actually a fly, but a planthopper. There is one generation of SLF per year. The eggs are laid in the fall (September to November) and hatch in the spring (late April to June). Egg masses are laid on smooth surfaces (trees, outdoor equipment, vines, posts, etc.) and protected with a mudlike covering. Egg masses usually contain around 35–40 eggs each (Figure 1A). Females can lay at least two egg masses. After hatching and before reaching adulthood, SLF goes through four immature (nymph) stages. Nymphs are small (⅛ to ½ inch) and can be hard to find (Figure 1B). The first three stages are all black with white spots, and the last is red with white dots and black stripes (Figure 1C). All nymphs are highly mobile and are strong jumpers. SLF adults emerge in July and are active until the first hard frost. This is the most obvious
and easily detectable stage because they are large (~1 inch) and mobile. Adults have black bodies with brightly colored hindwings. Only the adults can fly, and this is most commonly observed in the afternoon on warm and sunny days. SLF forewings are gray with black spots; the tips of the wings are black with gray veins; and their hindwings are red, black, and white. Because SLF adults walk more than fly, their wings usually remain closed (Figure 1D). Splayed wings can often be a sign of pesticide poisoning (Figure 1E).

**Feeding Damage**

SLF feed on plant phloem tissue (sap) using a piercing-sucking mouthpart. Current research suggests that they prefer plants with significant turgor pressure, which could help explain why they favor grapevines. SLF utilize the nutrients provided by the plant and also rely on bacteria in their guts to help digest sap. When SLF feed in high numbers on grapevines, photosynthesis and sap flow in the plant is reduced. Heavy SLF feeding can also decrease the amount of carbohydrates (i.e., starch) and nitrogen stored in root tissues in the fall, which might compromise vine health and growth in the following year. Reductions in macro- and micronutrient concentrations in leaf tissues were also reported by the end of the season following heavy SLF feeding. Research is still in progress to establish action thresholds for SLF, though this will likely be dependent on age, variety, location, and baseline health of the vine.

As SLF feed, they ingest large quantities of sap, filtering the needed nitrogen and proteins and excreting excess levels of sugars and water as waste products (much like aphids, scales, and other sucking insects). This excrement, called honeydew, accumulates around areas where SLF are feeding. On sunny days, you may be able to see honeydew falling from trees. Honeydew can be attractive to ants, wasps, bees, and other sugar-loving insects. As the honeydew builds up, it is often colonized by sooty mold fungi. Sooty mold doesn’t directly harm plants or the surfaces it grows on, but it does act as a barrier on the leaf to block photosynthesis. Under high numbers of SLF, understory plants may die back because of sooty mold buildup. On grapevines, the trunk, cordons, and leaves may begin to turn black with sooty mold. Sooty mold can only persist with the honeydew to feed on and will not infect the grapevine itself. There are currently no recommendations for removing sooty mold from grapevine trunks or cordons. Sooty mold is seldom recorded on the clusters and has not been reported as a problem for marketability or wine taint. We do not yet know if honeydew on clusters may increase rot infection.

Based on data from 2018 and 2019, increasing levels of SLF on *V. vinifera* vines has a significant correlation with reduced clusters per shoot the following spring. Our data suggest that SLF feeding may reduce the hardiness of the vine and potentially increase bud or vascular tissue (i.e., phloem and xylem) susceptibility to winter injury. As such, evidence of SLF damage to vines may only be present in colder winter conditions where the vines experience a higher likelihood of freezing damage. If you had high levels of SLF feeding in the summer or fall, you should evaluate bud injury before pruning the vines; moderate to high levels of bud injury require differing pruning strategies, such as increasing the number of buds retained to compensate for bud mortality or renewing trunks.

![Figure 2. The average number of SLF per vine from 2018 to 2020 across eight different vineyards in Berks County, Pennsylvania.](image-url)
**Vineyard Phenology and Spatial Distribution**

SLF are voracious feeders and can be extremely abundant as adults in vineyards. Adults start to appear in vineyards in August, but high populations are not typically observed until mid- to late September (Figure 2). For vineyards that are first experiencing SLF, this phenology is typically shifted later into the season—you may not see large numbers invade the vineyard until October. After one or two years, SLF typically invade vineyards earlier in the season (late August). More important, the majority of an SLF population within a vineyard is observed on the edge; on average, 54 percent of the SLF population is within the first 50 feet of the vineyard edge. Depending on the landscape surrounding the vineyard, the edge of the vineyard may account for even more SLF (upward of 80 percent of the population). Most SLF are observed feeding on the shoots, though later into the season more can be found on older wood (e.g., trunk and cordon). The majority of adult SLF observed in vineyards are female.

Egg masses are often found on the edge of the vineyard, but this is much less extreme than adults. Research suggests that SLF prefer to lay next to an existing egg mass, which means that the eggs are often found in clumped distribution (data provided by Lauren Briggs, Penn State). Most commonly, eggs are observed on the undersides of vines (thick cordons, below graft union, etc.), angled posts, and within nongalvanized metal posts.

**Seasonal Host Phenology**

SLF has a broad host range and has been recorded feeding on over 70 different plant species. Despite this wide host range, some plants appear to be more favorable than others. Whether a plant is heavily fed on appears to be highly dependent on what is available in the nearby landscape, the health of the plant, the time of year, and how long SLF have been present in the area. Nymphs, in particular, seem to have an especially large host range, whereas adults seem to depend more on certain hosts. Table 1 provides the key plant hosts of SLF and the time at which they are most likely to be found on these hosts, and it may help you identify problem areas with SLF adjacent your vineyard. The plants shown do not represent a comprehensive list of all potential hosts of SLF, but rather the most likely transition of SLF through the season. As plants begin to go dormant for winter, they are less likely to serve as a host for SLF. The patterns in host use may change with varying weather conditions, by region, and from other factors. Tree-of-heaven is a strongly preferred host; however, it is not required for SLF development.

**Monitoring**

As mentioned above, SLF utilize a large range of plant hosts. We recommend you monitor your vineyard and the wood edge for SLF on a regular basis (at least weekly), especially when adults are found from August to November. In the early summer, SLF nymphs are small and can be difficult to see. Nymphs tend to feed on softer tissue (at the tops of trees and herbaceous plants) and are often found on the undersides of leaves. Adults will be present on the trunks of trees and can be seen flying and gliding around where they are feeding. If you have not yet detected SLF in your vineyard, scouting for and monitoring tree-of-heaven or other hosts listed in Table 1 is the best place to start. A comprehensive guide on identification and removal of tree-of-heaven can be found on the Penn State Extension website. If there are

</table>
other highly desirable hosts nearby, we recommend you focus on monitoring and potential treatment on those plants. Monitoring plants can be done using either visual checks or tree traps wrapped around the trees (see below for more information on trapping). Treating ornamental trees can be done with either systemic or contact insecticides, depending on the plant type, whether SLF is feeding on the plant (or just using it as a launch point), and how long SLF is likely to be there. Our guide for landscape professionals can help you decide which approach is best.

Biological Control

Currently, there are no known natural enemies of SLF that are thought to reduce populations in the United States. Some generalist predators (spiders, praying mantises, parasitoids, etc.) will attack and eat SLF. Additionally, two species of fungal pathogens have been identified attacking SLF in Pennsylvania. One species, *Beauveria bassiana*, has been the recent focus of research for SLF management. This pathogen is commercially available as a biopesticide and can be sprayed to kill insect pests. In 2020 we evaluated the use of *B. bassiana* in woodlots adjacent to vineyards to reduce SLF populations. So far, these applications did not suggest control of SLF and we do not currently recommend *B. bassiana* for use in or around vineyards. Research is continuing to further optimize the use and formulations of *B. bassiana*. Researchers have also been exploring the native region of SLF to search for natural enemies to release in the United States, and these are currently undergoing evaluations in USDA quarantine facilities.

Cultural Control

Removal of Attractive Host Plants

If tree-of-heaven is found on or near the vineyard, it could be a source of SLF populations. However, we currently have no data on whether insecticide treatment or removal of tree-of-heaven will reduce populations of SLF. Some growers have had good luck with treating the tree-of-heaven with the systemic insecticide dinotefuran, and others have felt this offered little control (H. Leach, personal communication). Most likely, this is dependent on the size of the SLF population surrounding the vineyard and the presence of other attractive or suitable hosts. If removing tree-of-heaven, you must use herbicide. Failure to use effective herbicide on this tree will result in more tree-of-heaven being quickly produced from the roots and stumps. Be mindful of herbicide applications on tree-of-heaven, as grapevines are highly sensitive to herbicide drift.

Exclusion Netting

Over-the-row exclusion netting can be used to protect vines from SLF. Our research suggests that this netting can reduce SLF by up to 99.8 percent on the vines. Note that unlike over-the-row bird netting, this netting will need to be secured tightly on the sides and bottom to exclude SLF (Figure 3). In addition, to prevent entry of adult SLF, exclusion netting needs to be of a finer mesh than what is commonly used for bird netting. SLF may attempt to feed through the netting when the shoots

Figure 3. Exclusion netting (DrapeNet, Chazy, New York) used to protect vines from SLF. Note that this netting is tightly closed on the sides and bottom to prevent entry by SLF.
contact the netting on the top and sides, but this was seldom observed in our studies. While we did not observe difference in disease pressure from downy mildew or bunch rot, sugar content of the fruit was slightly lower (0.5° Brix on average), likely due to decreased light penetration to the canopy.

We are also currently researching the use of large wall structures as a barrier to SLF flight into the vineyard. This research is still in progress, but early data suggest this is a promising method for managing hotspot areas around the vineyard.

Using Traps
Placing circle traps around trees or banding trees with sticky tape can be useful monitoring tools for vineyards that have not yet detected SLF. However, use of traps is not a recommended control tactic around vineyards, as it is very unlikely to reduce the population. If using sticky bands, bycatch of nontarget insects (bees, butterflies, natural enemies, etc.), birds, and mammals (squirrels, bats, etc.) is likely. A wildlife barrier (e.g., window screening) should be built over the trap to prevent this bycatch. More details on trapping can be found on the Penn State Extension website.

Mechanical Destruction of Eggs
Scraping SLF egg masses and placing them permanently in an alcohol solution (e.g., rubbing alcohol, hand sanitizer) and physical destruction of eggs (smashing) are other approaches to kill SLF. Destruction of eggs might help reduce nymph populations in the spring, but it may not reduce or prevent SLF from infesting a vineyard, especially during the adult stage. It is important to remember that SLF lay their egg masses on many surfaces, including posts, trees, outdoor equipment, and furniture. In vineyards, they are found most commonly underneath cords, on the vines, and on metal and wooden posts (Figure 4). In addition, the majority of egg masses laid on trees are found above a reachable distance (8 feet). As a result, destruction of egg masses is unlikely to affect the bottom-line population in the vineyard. However, some vineyards have reported consistent large numbers of egg masses within their nongalvanized metal posts. Burning these posts with a propane torch, without damaging the grapevine, is a quick way to destroy many egg masses. If you are scraping the egg mass, we recommend you use a hard, flat tool (e.g., putty knife, plastic card) and scrape the egg mass downward into a container. Once finished, submerge all egg masses in alcohol. They can also be smashed, but you need to be sure you are applying pressure to the entire egg mass, or you may miss some eggs. Eggs burst open when they are smashed.

Chemical Control

Egg Masses
Based on studies done from 2018 to 2020, some insecticides have ovicidal action. All studies were done on intact egg masses (with covering) in February to April. Of the nine insecticides evaluated, only Lorsban Advanced (chlorpyrifos) at the dormant rate offered 100 percent mortality to the egg mass. JMS Stylet Oil (paraffinic oil) at a 3–5 percent rate offered control ranging from 50 to 80 percent mortality, with the higher rates offering greater control (please consult the product label for rate guidance). Note that control mortality in these studies was up to 35 percent. For the same reasons described above, using ovicides in vineyards for control of SLF is often not recommended. First, egg masses can be found throughout the landscape, including the vineyard, the pole barn, the woodlot, and your neighbor’s property. Second, the efficacy of ovicides is greatly dependent on coverage; good coverage on hidden egg masses (e.g., beneath peeling bark) may be difficult. Third, efficacy of available insecticides is better for nymphs than egg masses, making nymphs an easier and more successful target. That being said, the use of ovicides could be appropriate in your situation. If using Lorsban, note that it has specific label restrictions and is not currently labeled for SLF control. Lorsban Advanced can be applied prebloom for control of brown mar-

mated stink bug, cutworm, mealybug, and scale. Only one application of chlorpyrifos is allowed per season. Chlorpyrifos can be phytotoxic, so avoid applications after budbreak.

**Nymphs**

Limited information is available on the threat that the immature stages of SLF (nymphs) pose to grapevines. In general, low populations of nymphs are observed in vineyards and often occur when high numbers of eggs were deposited on the vines and posts in the fall. The nymphs are susceptible to a broad range of insecticides, including those that might be used for Japanese beetle. It is still important to monitor for populations of nymphs in your vineyard and apply treatment as needed. In some cases, spot treatments may only be needed for dense populations of nymphs (i.e., more than 10–50 per vine). Nymphs have not been observed reinfecting vineyards like adults do, so typically only one application of insecticide is necessary (if at all). Residual activity is not needed for the nymphs, so short-acting compounds (e.g., zeta-cypermethrin, malathion, carbaryl) are recommended.

**Adults**

Adults will most likely appear in your vineyard beginning in late August, but they could arrive as early as late July. Many of the same insecticides that are effective at killing the nymphs are also good at controlling the adults: dinotefuran (Scorpion, Venom), imidacloprid (Admire Pro), beta-cyfluthrin (Baythroid), bifenthrin (Brigade, Bifenture), fenpropathrin (Danitol), thiamethoxam (Actara), carbaryl (Carbaryl, Sevin), and zeta-cypermethrin (Mustang Maxx). In general, we recommend using longer-residual products during the heaviest period of reinestation, which tends to be in September. Be mindful of preharvest intervals (PHIs) on the labels and your harvest date. Pyrethroids have the longest residual activity evaluated to date. Closer to harvest, you may need to apply products with shorter PHIs, which generally don’t have long residual activity for SLF. Therefore, these products may require repeated applications for adequate control (Table 2).

In 2020 we found a cannon sprayer (CIMA Cannon Spray Head, BDI Machinery, Macungie, Pa.) to be equally effective at killing SLF with a border sprayer, compared to spraying the entire vineyard with an over-the-row sprayer.

*Longevity of product can vary depending on weather conditions, coverage, etc. The longevity listed is what we determined in our field insecticide studies using four-year-old vines.

**Bifenture EC has a 24(c) label amendment for SLF in Pennsylvania to apply twice (once at preharvest and once at postharvest or twice at postharvest) at the maximum labeled rate. The PHI is 30 days.

Registrations and labels may change, and human error is always possible. You must read and follow the most current label before applying any pesticide. The trade names listed here are examples of products that have been tested on SLF; this list is not an endorsement of any product. Other products with the same active ingredient and rates will likely offer similar control as what is shown above.
Before applying any insecticide, you must read and follow the label to be sure you are making a legal application with timings and rates, and have appropriate personal protection equipment (PPE), reentry intervals (REIs), preharvest intervals, and warnings for pollinator protection. Visit www.CDMS.net to check for the most up-to-date label information. While SLF have only one generation per year, you should rotate the use of different insecticide classes or modes of action for SLF throughout the season to reduce the likelihood of insecticide resistance. Be mindful that you are preventing insecticide resistance for not only SLF but also other common vineyard pests such as fruit flies. The use of pyrethroids and other broad-spectrum insecticides may flare up secondary pests such as mites, leafhoppers, or aphids.

Additional products have been tested against SLF and have not shown great efficacy. They are not listed in Table 2 and include the following active ingredients: indoxacarb (Avaunt), phosmet (Imidan), Assail (acetamiprid), and chlorantraniliprole (Altacor).

Postharvest Management
After mating and laying eggs in the fall, SLF have been observed to become less active and eventually die. Typically, no more SLF are observed in vineyards after the first week of November. After harvest, it is likely that you will continue to have SLF populations in your vineyard, and we recommend postharvest insecticide applications. In this case, you can use products with a longer residual for longer control and reduce the number of applications you need. After egg masses have been laid (late November), scout your vineyard and surrounding wood edge for egg masses to identify potential hotspot areas for nymphs next year.

Building and Tasting Room Control
Many wineries that have outdoor tasting areas have reported nuisance problems from SLF and complaints from customers. Typically, this only occurs at problematic levels during the active flight period (mid-September). If you can identify a main source of the SLF population (e.g., a nearby tree), treating this source with insecticide could alleviate the flight activity. Because this flight period is relatively short, a long-lasting pyrethroid (e.g., bifenthrin or beta-cyfluthrin) could be used on the plants or structures where SLF are found crawling or flying. Keep in mind that you must use insecticides labeled for this purpose. Some wineries have also utilized exclusion netting or shade cloth as a way to keep SLF out of the outdoor tasting areas with good success. In general, it is a good practice to encourage customers to be aware of SLF and check their vehicles and belongings before they travel so that they do not bring SLF elsewhere.

Quarantine Regulations
If you conduct business within the SLF quarantine in Pennsylvania and move products, vehicles, or other conveyances within...
or out of the quarantine (Figure 5), the Pennsylvania Depart-
ment of Agriculture requires that you obtain an SLF permit.
The permit training is free and can be taken online. The per-
mit ensures you and all employees have been properly trained
on the identification and biology of SLF, and your vehicles and
shipments are inspected and found to be free of SLF before mov-
ing. SLF adults can be found crawling all over many surfaces,
including harvest bins, tractors, trucks, etc., so you must be sure
that all of these materials are free of SLF. Businesses receiving
shipments of fruit or juice within the quarantine zone must
also hold an SLF permit. If a business that needs an SLF permit
is caught without one, fines may be issued. Specific questions
about the permit can be directed to SLFPermit@PA.gov. Other
states have quarantines and permit requirements for this pest,
and there is reciprocity of these permits between states.

Summary

1. SLF may cause significant damage to grapevines, including
   increased susceptibility to winter injury, reduced carbohy-
   drate and nitrogen levels in root tissues, and reduced yield.
   The degree of damage is likely dependent on the level of SLF
   infestation, overall health of the vine, winter conditions, and
   other stressors placed on the vine.

2. Adult SLF are the most problematic in vineyards and arrive
   from late August through November. Nymphs are typically
   not problematic and should only require one insecticide
   application, if any.

3. If you don’t yet have SLF or only have low populations of SLF,
   monitor tree-of-heaven and other highly desirable hosts (e.g.,
   wild grapevines, black walnut) surrounding your vineyard to
   find potential sources of SLF.

4. If SLF is present in large numbers (more than 10–20 per
   vine), consider applying insecticides or utilizing exclusion
   netting. Finding only a few SLF throughout the vineyard may
   not warrant a spray. Targeted insecticide sprays at the border
   of the vineyard (~50 feet into the vineyard) are effective at
   reducing SLF.

5. After applying insecticides, continue to monitor and spray
   as needed. SLF are susceptible to many insecticides, but they
   quickly reinvade your vineyard from the surrounding land-
   scape, making them difficult to control.

6. If you had significant feeding from SLF in the summer or fall,
   check bud mortality and consider leaving more buds on the
   vine when pruning to avoid winter injury.

7. If you’re conducting business in the Pennsylvania quaran-
   tine zone, you must get an SLF permit from the Pennsylvania
   Department of Agriculture.

We encourage you to stay up to date by checking our website,
attending regular extension meetings, or contacting your local
extension educator. Research on this important pest is ongo-
ing, and information may change as we learn more about this
insect. Be sure to check online for updated versions of this fact
sheet. Last updated by Heather Leach and Michela Centinari,
April 2021.
